## Learning from structure solution: An enhanced solid-state Mg electrolyte

*Tuesday, 8 December 2020 15:25 (25 minutes)*

All-solid-state batteries based on magnesium are considered for the use in mobile applications as well as to store energy from “renewable” intermittent energy sources. Recently, a solid state magnesium ion conductor,  $\text{Mg}(\text{en})\text{1}(\text{BH}_4)_2$  (en stands for ethylenediamine), obtained from  $\text{Mg}(\text{BH}_4)_2$  :  $[\text{Mg}(\text{en})_3(\text{BH}_4)_2]$  2:1 mixture, was reported to have an exceptionally high magnesium ion conductivity of up to  $6 \cdot 10^{-5} \text{ S} \cdot \text{cm}^{-1}$  at  $70^\circ \text{C}$ . Here we show that this synthesis actually yields a mixture of  $\text{Mg}(\text{en})\text{1.2}(\text{BH}_4)_2$  and amorphous  $\text{Mg}(\text{BH}_4)_2$ . The latter was often neglected in previous investigations, though it was shown recently that its dynamics have a positive influence on the conductivity. The structure of  $\text{Mg}(\text{en})\text{1.2}(\text{BH}_4)_2$  has been solved from single crystal X-ray diffraction in space group P-1 and confirmed by neutron powder diffraction on isotopically substituted  $\text{Mg}(\text{en})\text{1.2}(\text{11BD}_4)_2$ . Its structure shows three Mg atoms with coordination numbers 4, 5 and 6, the  $\text{BH}_4$  groups behaving as terminal and bridging ligands, and en chelating and bridging Mg atoms. This complexity makes the structure solution virtually impossible from powder diffraction data. Thermal decomposition of  $\text{Mg}(\text{en})\text{1.2}(\text{BH}_4)_2$  goes through an intermediate formation of the previously unknown  $\text{Mg}(\text{en})_2(\text{BH}_4)_2$ , its structure was solved from synchrotron X-ray powder diffraction, complemented by DFT optimization.
