## Exploring The Structure of MAPbI<sub>3</sub> Across its Phase Diagram Using Neutron Spectroscopy, Thermophysical Properties and First-Principles Simulations –A Closer Look at High Pressures

Tuesday, 21 March 2023 12:10 (20 minutes)

Hybrid Organic-Inorganic Perovskites (HOIPs) have attracted an unprecedented attention as promising candidates for the next-generation of photovoltaic materials due to their exceptional energy conversion rates. Moreover, a better understanding of their remarkably soft atomic structures and their stabilization mechanisms is still necessary [1,2]. In this contribution we present an extensive study on the structure of the prime example of HOIPs methylammonium lead iodide (MAPbI<sub>3</sub>) using a wide variety of radiation-scattering techniques validated by first-principles simulations across the temperature and pressure axes. We shall first introduce a model-selection protocol using inelastic-neutron scattering, thermophysical properties like the heat capacity, and density-functional theory simulations [3]. This protocol was successfully implemented for MAPbI<sub>3</sub>, showing that an alternative *P1* structure is statistically sounder than the crystallographic *Pnma* model. Furthermore, we present the first results of high-pressure radiation-scattering experiments performed on MAPbI<sub>3</sub> together with a new set of extensive *ab initio* molecular dynamics simulations. These findings will pave the way towards a better understanding of the fundamental yet scarcely explored role played by pressure in the stability of MAPbI<sub>3</sub>.
